SOLVING

Solvers
considerations

CONCLUSIONS

- Modelling languages facilitate the expression of an SP model and its solution but..
- SP models are not just the decision models, and the steps to obtain a reliable result are more than just the modelling of the decision process
 - Decision modelling
 - Randomness modelling (Scenario Generation)
 - Problem investigation (back testing/stress testing)
- We propose a framework that assists in all those steps of SP modelling

SOLVING

Solvers
considerations

CONCLUSIONS

- We first consider the linear programming problem:

$$\begin{aligned} Z &= \min cx \\ \text{subject to } Ax &= b \\ x &\geq 0 \end{aligned}$$

$$\text{where } A \in R^{m \times n}; c, x \in R^n; b \in R^m$$

- Let (Ω, F, P) denote a (discrete) probability space where $\omega \in \Omega$ denote the events. Let us denote the realizations of A, b, c for a given ω as:

$$(A^\omega, b^\omega, c^\omega) = \xi^\omega \quad \text{or} \quad \xi(\omega)$$

Distribution problems (EV)

INTRODUCTION

SP MODELLING

SG in SPInE

Scenario
Generation
Computational
Architecture

INVESTIGATION

Simulation and
testing
Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- The distribution of the objective function value for different realisations of the random parameters and also for the expected value of such parameters are broadly known as the distribution problem
- **The Expected Value Problem**
 - The Expected Value (EV) model is constructed by replacing the random parameters by their expected values
 - Such EV model is thus a linear program, as the uncertainty is dealt before it is introduced

Distribution problems (EV)

INTRODUCTION

SP MODELLING

Modelling
Languages
SAMPL

SG in SPInE

Scenario
Generation

Computational
Architecture

INVESTIGATION

Simulation and
testing

Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- We can reconsider the previous problem as EV:

$$(\bar{A}, \bar{b}, \bar{c}) = \bar{\xi} = E[\xi^\omega] = \sum_{\omega \in \Omega} p^\omega \xi^\omega$$

$$Z_{EV} = \min \bar{c}x$$

subject to

$$\bar{A}x = \bar{b}$$

where $p^\omega = P(\xi(\omega))$ denotes the probability associated with the realisation $\xi(\omega)$.

- Let x_{EV}^* denote the optimal solution to the above problem

Distribution problems (EV)

INTRODUCTION

SP MODELLING

Modelling
Languages
SAMPL

SG in SPInE

Scenario
Generation
Computational
Architecture

INVESTIGATION

Simulation and
testing
Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- This solution can be evaluated for all possible realisations $\omega \in \Omega$
- We can thus determine the corresponding objective function values and compute what is called the **expectation of the expected value** solution

$$Z_{EEV} = E[c^\omega x_{EV}^*]$$

- If an ω exists such that x_{EV}^* is not feasible for some realisations of the random parameters, we set:

$$Z_{EEV} \rightarrow +\infty$$

Distribution problems (WS)

INTRODUCTION

SP MODELLING

Modelling
Languages
SAMPL

SG in SPInE

Scenario
Generation
Computational
Architecture

INVESTIGATION

Simulation and
testing
Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- Wait and See Problems
- Wait and See (WS) problems assume that the decision-maker is somehow able to wait until the uncertainty is resolved before implementing the optimal decisions
- The corresponding problem (and solutions) is stated as:

$$Z^{\omega} = \min c^{\omega} x$$

$$A^{\omega} x = b^{\omega}$$

$$Z_{ws} = E[Z^{\omega}] = \sum_{\omega \in \Omega} Z^{\omega} p^{\omega}$$

Recourse Problems (HN)

INTRODUCTION

SP MODELLING

Modelling

Case studies

SOLVING

Solvers
considerations
CONCLUSIONS

- **Recourse Problems**
- The term Here and Now (HN) is often used to refer to stochastic programming problems, reflecting the fact that decisions are taken before perfect information on the states of nature is revealed
- The classical stochastic linear program with recourse separates the model's decision variables into
 - **first stage** strategic decisions which are taken facing future uncertainties
 - **second stage** recourse (corrective) actions, taken once the uncertainty is revealed

Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

Recourse Problems (HN)

- The formulation of the classical two-stage SP model with recourse is as follows:

$$\begin{aligned} Z_{HN} = \min \quad & cx + E_{\omega}[Q(x, \omega)] \\ \text{subject to} \quad & Ax = b \\ & x \geq 0, \end{aligned}$$

where:

$$\begin{aligned} Q(x, \omega) = \quad & \min f(\omega)y(\omega) \\ \text{subject to} \quad & D(\omega)y(\omega) = d(\omega) + B(\omega)x \\ & y(\omega) \geq 0. \\ & \omega \in \Omega \end{aligned}$$

Scenario Based RP

INTRODUCTION

SOLVING

Solvers
considerations

CONCLUSIONS

- Giving that the random parameter vector ξ^ω has discrete distribution
- The event parameter ω takes the range of values $\omega = 1, \dots, \#(\Omega)$
- There are associated probabilities p^ω and random parameter vector realisations ξ^ω such that:

$$\sum_{\omega \in \Omega} p^\omega = 1 \quad \text{and} \quad \Xi = \bigcup_{\omega \in \Omega} \xi^\omega$$

Computational
Architecture

INVESTIGATION

Simulation and
testing

Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- \mathcal{E} is the set of all random parameter vectors realisations and is often called the *set of scenarios*
- The uncertainty defines a structure in the form of an event tree, which represents the possible sequence of realisations (scenarios) over the time horizon, with their probability
- When the event tree is explicitly given, we refer to the model as a *scenario based recourse problem*

Scenario Based RP

- The event tree of a T-stages recourse problem:

- All the values of the realizations of random parameters (scenarios) ARE to be defined

SOLVING

Solvers
considerations

CONCLUSIONS

- AMLs allow to conveniently express MPs in a format both easy to understand and that can be processed by a solver
- SPs have different requirements, both in language constructs and in coupling with data
- The design of SAMPL extends an AML (in our case AMPL) to provide these additional constructs
- SPInE is the framework that deals with the second requirement (interpreting SAMPL and coupling to SGs)

AML concepts

- Mathematical Programming:
 - Modeler's understanding of the problem leads to "modeler's form"
 - Solvers accept a different format: "algorithmic form"
 - -> Algebraic Modelling Languages, AMPL being one of those
- It allows a separation between model and data, recommended for most applications

Introductory Example

- Deterministic, all parameters are known
- Introductory model: Dakota [J. Higle, S.W. Wallace, *Interfaces*, 2003]

Each product has
different requirements
in terms of resources

Sold items \leq Market
demand for that
particular class of
products

Introductory Example

SETS

| | Description |
|---|-------------|
| P | Products |
| R | Resources |

VARIABLES

| | |
|-------|--------------------------|
| X_r | Resource Acquisition (r) |
| Y_p | Production Levels (p) |
| Z_p | Sales Quantities (p) |

PARAMETERS

| | |
|----------|--------------------|
| C_r | Cost (r) |
| R_{rp} | Requirement (r, p) |
| S_p | Selling Price (p) |
| D_p | Market Demand (p) |

OBJECTIVE FUNCTION

$$\max \sum_{p \in P} S_p Z_p - \sum_{r \in R} C_r X_r$$

subject to :

$$X_r \geq \sum_{p \in P} R_{rp} Y_p \quad \forall r \in R$$

$$Z_p \leq Y_p \quad \forall p \in P$$

$$Z_p \leq D_p \quad \forall p \in P$$

CONSTRAINTS

- Five types of entities: SETS, PARAMETERS, VARIABLES OBJECTIVE(s), CONSTRAINTS,
-> AMLs are to be able to handle them

AMPL Considerations

CONCLUSIONS

- Distinction between declarations and definitions
- Declaration of the model:

SETS

| | Description |
|---|-------------|
| P | Products |
| R | Resources |

VARIABLES

| | |
|-------|--------------------------|
| X_r | Resource Acquisition (r) |
| Y_p | Production Levels (p) |
| Z_p | Sales Quantities (p) |

PARAMETERS

| | |
|----------|--------------------|
| C_r | Cost (r) |
| R_{rp} | Requirement (r, p) |
| S_p | Selling Price (p) |
| D_p | Market Demand (p) |

```

set products;
set resources;
var amountbuy{r in resources} >=0;
var amountprod{p in products} >=0;
var amountsell{p in products} >=0;
param cost{resources};
param prodreq{resources,products};
param price{products};
param demand{products};
    
```

AMPL Considerations

OBJECTIVE FUNCTION

$$\max \sum_{p \in P} S_p Z_p - \sum_{r \in R} C_r X_r$$

```
maximize wealth : sum{p in products} price[p]*amountsell[p]
- sum{r in resources} cost[r]*amountbuy[r];
```

subject to :

$$X_r \geq \sum_{p \in P} R_{rp} Y_p \quad \forall r \in R$$

$$Z_p \leq Y_p \quad \forall p \in P$$

$$Z_p \leq D_p \quad \forall p \in P$$

CONSTRAINTS

```
subject to
balance{r in resources}: amountbuy[r] >= sum{p in products}
prodreq[r,p] * amountprod[p];

production{p in products} : amountsell[p] <= amountprod[p];

sales{p in products}: amountsell[p] <= demand[p];
```

Extending AML for SP

- Stochastic Programming model considered as a MP model extended and refined by the introduction of uncertainty
- The probability distributions of model's random parameters are provided by models of randomness called Scenario Generators (SG)
- The SG to be used is specific to the particular optimisation problem under investigation
- SG provide the stochastic information in form of a Scenario Tree

Language requirements

- Scenario based recourse problems
 - Declaration of **random parameters**
 - Realizations given in the form of a **scenario tree**
 - **Stages** identify the sequence of the decisions
- Chance Constraint problems
 - Declaration of **individual chance constraint** with related reliability level
 - Declaration of **joint chance constraint** with relating reliability level
 - Declaration of **random parameters** in terms of scenarios or distributions

SOLVING

Solvers
considerations

CONCLUSIONS

- Dynamic structure needs to be further specified

-> Specification of tree structure AND grouping of decision variables into stages

SAMPL Dakota Model

- The same as deterministic Dakota, adding:

```
scenarioset scen:= low med high;
```

```
tree theTree:= twostage{3};
```

```
random param demand{products, scen};
```

```
probability param Prob{scen};
```

```
var amountbuy{r in resources, s in scen} >=0, suffix stage 1;
```

```
var amountprod{p in products, s in scen} >=0, suffix stage 2;
```

```
var amountsell{p in products, s in scen} >=0, suffix stage 2;
```

Variables are now
scenario-dependent

Stages

Scenario Generation

- SPInE is the interpreter for SAMPL language
- Random data definition:
 - In the example, explicit values for the realizations of the random vectors were provided
 - Those are usually obtained through the use of Scenario Generators
 - Direct connection to SGs is currently under implementation
 - Plug-ins architecture
 - SAMPL model declaration remains the same

Scenario Generation

- There are many well established methods - models for describing random parameters
- The models can be summarised as:
 - AR, MA , ARMA, ARCH, GARCH, ...
 - Regression: quantile, robust
 - SDEs, GBM
 - Forecasting: Parametric, nonparametric
 - Simulators: MCMC, HiddenMC, VECM, Bootstrap
- Real applications use Domain specialist's model / knowledge

CONCLUSIONS

SG Library – Basic concept

- Every scenario generator to be included has to implement the same (simple) interface
- Since different SG methods require different parameters/data, every SG Module has to be self-descriptive
- The interface specifies two types of methods:
 - Descriptive - “*meta-functions*”: return the description of the parameters of the SG
 - Functional - “*execution units*” i.e. To start the scenario generation

CONCLUSIONS

The screenshot displays the OptiRisk software interface. On the left, a 'Workspace Explorer' window shows a project structure with folders like 'TestWorkspace' and 'My Brand New Folder', and files like 'dilentries.xls', 'ALM.dat', and 'ALM.mod'. The main area is divided into a code editor and a properties window. The code editor contains SQL-like statements for table creation and reading, such as 'table tbl_liabs IN 'ODBC', 'alm.mdb': [tp], liabilities ~ liability;'. A 'Random parameters' dialog box is open, showing a dropdown menu for 'assetPrice' with options: 'Geometric Brownian Motion', 'Hidden Markov Chain', and 'Model defined'. A red circle highlights the dialog box, and a red arrow points from the dropdown menu to the code editor.

SAMPL

SG in SPInE

Scenario
Generation
Computational
Architecture

INVESTIGATION

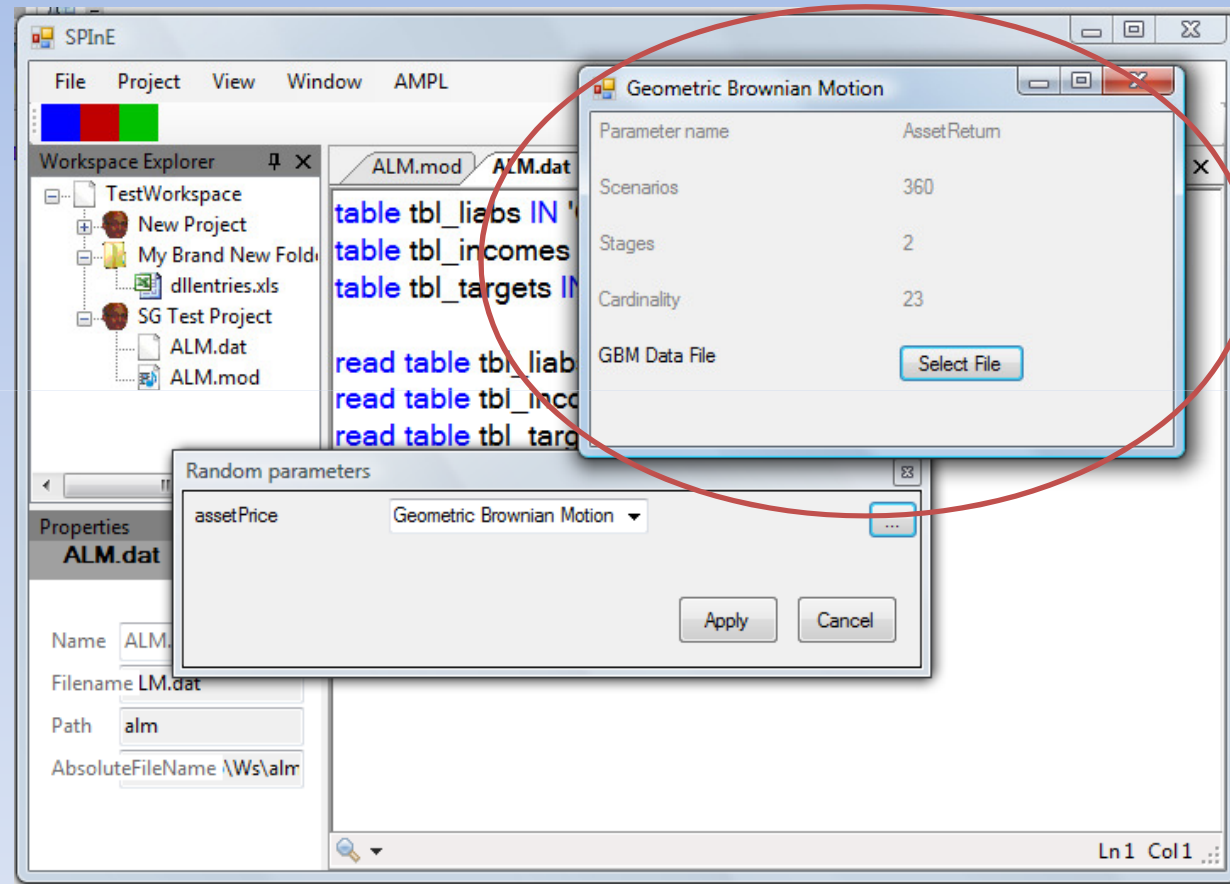

Simulation and
testing
Case studies

SOLVING

Solvers
considerations

CONCLUSIONS

- "Real world" scenarios is a large scenario tree, which is assumed to be the best available approximation of the stochastic process

Out of sample SG testing

(1) Generate Random Parameters with SG set 1 (under test)

(2) Solve HN Model

(3) Get realistic values for the stochastic process – from real world or from another SG

(4) Fix variables with solution obtained

(5) Solve sub-problems

(6) Collect and Analyze Results

Simulation and testing

- The design of the framework to allow various kind of testing is still in progress
- Natural approach seems to be the workflow one, in which a few specialised modules can be organized in a user defined way to perform potentially complex tasks

Generate Scenarios

Define SG set / variable bindings

Collect Data

Data Analysis is the final aim of simulation

Fix Variables

Define which variable is bound to which other

Solve Model

With specified solver / solver's settings

Solving SP Problems

- The solution of SP problems is difficult
- Decomposition based methods allow to greatly speed up the solution of the Here and Now (recourse) model
- SPInE includes three solvers:
 - FortSP: can use DEQ as well as Benders decomposition
 - FortSD: can use Stochastic Decomposition [Sen and Higle, 2000]
 - FortLD(*): uses Level Decomposition [Fabian, 2006]

Solving SP Problems

- As seen before, for simulation/testing there's often the need to fix the first stage variables and solve all the sub-problems
- In the important class of the two stage models, this leads to solve a lot of models that differ from each other just for a few parameters
- Those parameters are the stochastic ones in the second stage of the original model
- This can be viewed as a *family* of models

Solving SP Problems

- The use of *warm restart* usually helps in the solution of the sub-problems:
 - store the optimum basis factors information in a back up store,
 - retrieve the basis factor information from the back up store and continuing with processing.
- We find that in general the average number of iterations required to solve the problem from ‘scratch’ is much bigger than if starting from the neighbouring optimum solution
- SPInE is designed to invoke base restart functionalities of solvers – where present

Future Developments

- Work in progress:
 - Extend the SG library
 - Update the model instance format (currently SMPS)
 - Allow dynamic structure to be specified in the scenario generators
 - Implementation of the simulation/decision evaluation environment
 - Use of OpenMP to exploit multi-core/multi-processor computers, especially for simulation
